2024

Equation systems

- A set of of equations that share the same variables is called an *equation system*.
- For example:

$$x + y = 3 \tag{1}$$

$$2x - y = 1 \tag{2}$$

- Because both (1) and (2) share x and y, they form an equation system.
- lacktriangle We usually want to *solve* the system, i.e., find the values of x and y that satisfy both equations.

Solving equation systems

- There are several methods to solve equation systems.
 - Substitution
 - Elimination
 - Graphing
 - Matrices (we will see this later)
- Substitution is typically the most "mechanical" method.
 - Express one variable in terms of the other and substitute in the other equation.
- Elimination is more algebraic.
 - Add or subtract the equations to eliminate one variable.
 - Might involve multiplying one or both equations by a constant.

Solving the example system

■ Let's solve the example system:

$$x + y = 3$$
$$2x - y = 1$$

- We can solve this system by substitution.
 - \blacksquare From (1), we have y = 3 x.
 - Substitute this into (2):

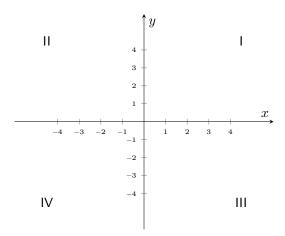

$$2x - (3 - x) = 1$$

 \blacksquare Solve for x and then substitute back to find y.

The Cartesian plane

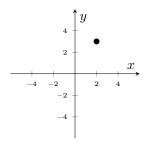

- The Cartesian plane is a two-dimensional space where we can plot points.
- It is formed by two perpendicular lines, the *x-axis* and the *y-axis*.
- The point where the axes intersect is called the *origin*.
- The axes divide the plane into four *quadrants*.

The Cartesian plane

Plotting points

- \blacksquare To plot a point, we use an ordered pair (x,y).
 - lacksquare x is the distance from the y-axis.
 - lacksquare y is the distance from the x-axis.
- For example, the point (2,3) is 2 units to the right and 3 units up from the origin. See below:

Linear equations

- The equations we've seen so far are *linear* equations.
 - They represent straight lines in the Cartesian plane.
- Linear equations can be written in the form y = mx + b.
 - lacksquare m is the *slope* of the line.
 - b is the y-intercept.

The Slope

- The ratio of the vertical change to the horizontal change.
 - It tells us how steep the line is.
 - The bigger the slope, the steeper the line.
- Requires two points (call them P_1 and P_2) on the line, with coordinates (x_1, y_1) and (x_2, y_2) .

about to use y=mx+b to figure out the slope of the line you just crossed

Figure 1: A meme

Intercepts

- The *y-intercept* is the point where the line crosses the y-axis.
 - This happens when x = 0.
 - lacksquare So, we set x=0 in the equation and solve for y.
 - In the equation y = mx + b, the y-intercept is (0, b).
- The *x-intercept* is the point where the line crosses the *x*-axis.
 - This happens when y = 0.
 - So, we set y = 0 in the equation and solve for x.

Graphing linear equations

- To graph a linear equation, we need to find two points on the line.
 - The easiest points are the intercepts.
 - We can also use the slope to find a second point.
- Example: graph the line y = 2x + 1.
 - It might be useful to draw a table of values.

$$\begin{array}{c|cc} x & y \\ \hline 0 & 1 \\ 1 & 3 \\ -1 & -1 \end{array}$$

Graphing the line

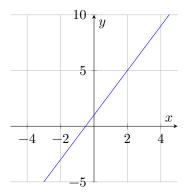

Figure 2: Plot of the equation y = 2x + 1

Upward-sloping and downward-sloping lines

- If m > 0, the line is "upward-sloping" or increasing.
 - \blacksquare As x increases, y also increases.
- If m < 0, the line is "downward-sloping" or decreasing.
 - \blacksquare As x increases, y decreases.

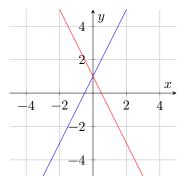

Figure 3: Upward-sloping and downward-sloping lines

Properties of slopes

- If m = 0, the line is horizontal.
 - \blacksquare y does not change as x changes.
- If $m = \infty$, the line is vertical.
 - lacktriangledown x does not change as y changes.
- If m = 1, the line has a 45-degree angle.
- Lines with the same slope are parallel.
- Lines with slopes that multiply to -1 are perpendicular.
 - \blacksquare This means that $m_1\cdot m_2=-1,$ or that $m_1=-\frac{1}{m_2}$ (the negative reciprocal).

The y-intercept

lacktriangle The point where the line crosses the y-axis.
